

Lab Summary Report

Name: Christian Farrel Tammel

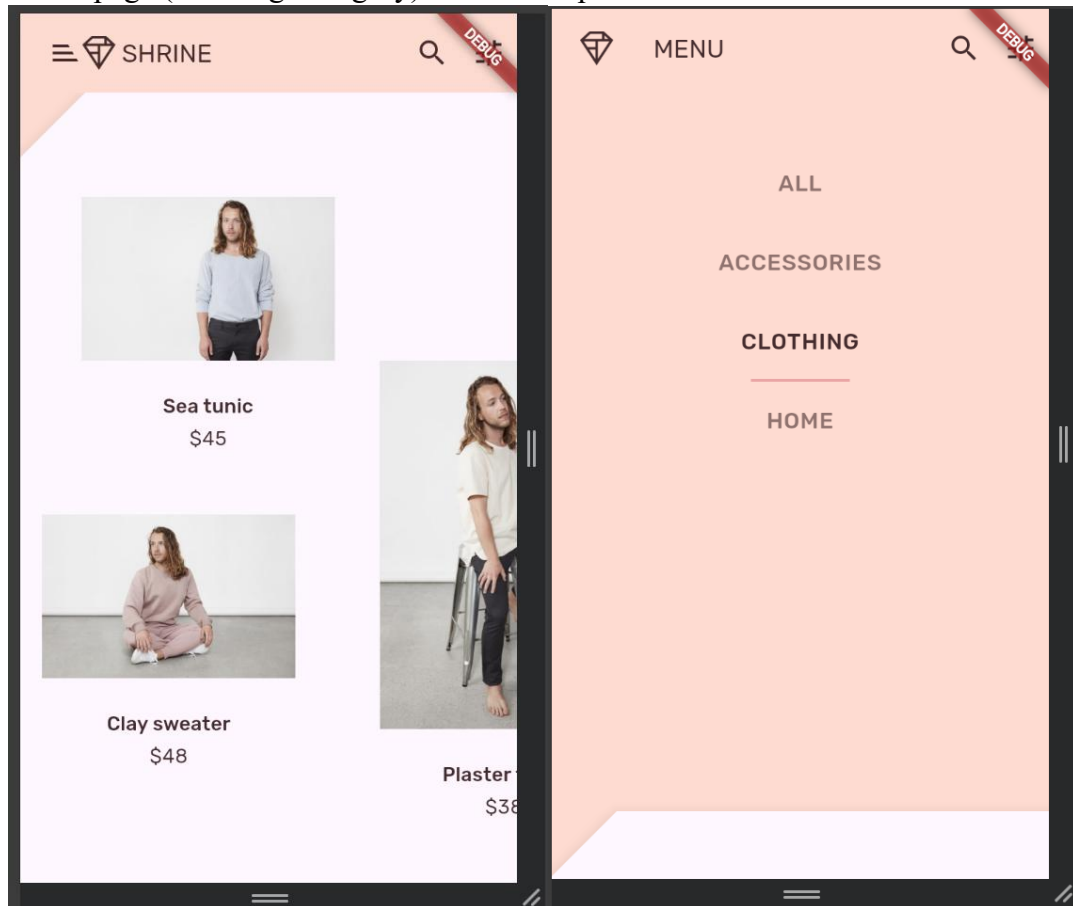

NIM: 2086022510011

Final Customized App Interface:

1. Log in page & Home page (All Category)

2. Home page (Clothing Category) & BackDrop

Reflection Question:

1. Design systems:
Flutter's ThemeData really simplify app-wide visual updates compared to hardcoding colors and styles into individual widgets because it centralizes design choices like colors, typography and component themes. Updating something inside ThemeData immediately change every visual properties across the whole app making every page looks consistent. If we instead hardcoded each and every visual properties inside its own widget, it would be frustrating to change the properties in each widget one by one if we want to change for example the app theme
2. State & Animation:
The BackDrop widget tells the parent class that the user has selected a category (callback (`_onCategoryTap`)). Then the parent class updates the current category selected by the user using `setState()`. After that the parent pass the filtered product list to the home page and that triggers the animated back drop when we press the category options
